How to Treat Opioid Use Disorder in the General Hospital Setting

Learning Objectives:
1) Diagnose Opioid Use Disorder, Opioid Intoxication, and Opioid Withdrawal
2) Determine whether a patient would benefit from Medication Assisted Treatment (MAT) initiation
3) Incorporate special considerations, metabolic profile, and any contraindications when choosing MAT

Step 1: Determine if Patient is in Acute Opioid Intoxication or Withdrawal (Table 1)
• Prioritize clinical stabilization of acute intoxication or withdrawal prior to doing an assessment for Opioid Use Disorder (see Table 1 for diagnosis of intoxication or withdrawal).
• If patient in active withdrawal, assess severity of withdrawal with clinical instruments such as the Clinical Opiate Withdrawal Scale (COWS), initiate medication-assisted management to ease withdrawal symptoms (see Step 4 and 5).
• If patient is acutely intoxicated:
  ▪ Do not initiate treatment of MAT until patient more stable clinically. Monitor patient for onset of withdrawal symptoms.
  ▪ Consider administration of naloxone, an opioid antagonist, if there are concerns of opioid overdose (see Table 1).

Table 1: Diagnoses of Opioid Intoxication and Opioid Withdrawal (Integrating DSM5 Criteria)

Vers. 02/23/2023
**Step 2: Familiarize Oneself with the Diagnosis of Opioid Use Disorder (OUD)**

- Diagnosis of Opioid Use Disorder in the inpatient setting is useful for linkage to ongoing treatment in the outpatient setting and engaging a patient with Medication-assisted Treatment (MAT). Initiating MAT in the inpatient setting has been shown in studies to improve relapse prevention.
- The DSM 5 defines Opioid Use Disorder as a problematic pattern of opioid use leading to problems or distress, with at least two of the following occurring within a 12-month period:
  - Opioids are often taken in larger amounts or over a longer period than was intended.
  - There is a persistent desire or unsuccessful efforts to cut down or control opioid use.
  - A great deal of time is spent in activities necessary to obtain the opioid, use the opioid, or recover from its effects.
  - Craving, or a strong desire or urge to use opioids.
  - Recurrent opioid use resulting in a failure to fulfill major role obligations at work, school, or home.
  - Continued opioid use despite having persistent or recurrent social or interpersonal problems caused or exacerbated by the effects of opioids.
  - Important social, occupational, or recreational activities are given up or reduced because of opioid use.
  - Recurrent opioid use in situations in which it is physically hazardous.
  - Continued opioid use despite knowledge of having a persistent or recurrent physical or psychological problem that is likely to have been caused or exacerbated by the substance.
  - Tolerance, as defined by either of the following:
    - A need for markedly increased amounts of opioids to achieve intoxication or desired effect
    - A markedly diminished effect with continued use of the same amount of an opioid (Note: This criterion is not considered to be met for those taking opioids solely under appropriate medical supervision.)
  - Withdrawal, as manifested by either of the following:
    - The characteristic opioid withdrawal syndrome
    - Opioids (or a closely related substance) are taken to relieve or avoid withdrawal symptoms. (Note: This criterion is not considered to be met for those individuals taking opioids solely under appropriate medical supervision.)
- Severity: mild = 2–3 symptoms; moderate = 4–5 symptoms; severe = 6 or more symptoms

**Step 3: Assess the Patient for OUD Treatment**

- Distinguish whether a patient has OUD using diagnostic criteria above versus whether the patient is appropriately using prescribed opioid prescriptions.
Be aware of any implicit biases you may be experiencing in assuming a patient has opioid use disorder, and be open to understanding their experience of opioid use.

Note that physical tolerance does not equal psychological tolerance and opioid misuse.

An assessment for OUD Treatment should include:

- A medical and psychiatric history, a full substance use history, and an evaluation of family and psychosocial supports
- Frequency of opioid use and route of administration (e.g., oral, intravenous, intranasal) can help gauge likelihood of severe withdrawal or possible infections, which will influence further testing.
- Prescription opioid use history checked through the state's Prescription Drug Monitoring Program (PDMP), where available, to detect unreported use of other controlled medications, such as benzodiazepines or other opioid medications, that may interact adversely with the treatment medications
- Previous attempts to stop using opioids, type of medication and non-medication strategies used, and response to treatments

Review patient labs as part of the assessment:

- Test urine for opioids, alcohol, and other drugs, such as benzodiazepines.
- Conduct a complete blood count (especially if any signs of bacterial infection such as endocarditis).
- Assess for hepatitis B/C and HIV for those who inject intravenously.
- Offer vaccination for patients who inject drugs and have negative hepatitis B serology.
- Consider testing for syphilis and tuberculosis if indicated.
- Assess liver and kidney function with liver enzyme, serum bilirubin, and serum creatinine blood tests to adjust MAT dosing or defer from initiation (in case of liver failure/significant cirrhosis).
- Pregnancy testing for women of reproductive age

Step 4: Determine Best MAT Option for Patient and Initiate Treatment (see Table 2)

- General Considerations for MAT
  - Buprenorphine and naltrexone can block the effects of other opioids taken concurrently and thus can induce opioid withdrawal.
  - Naltrexone should not be given until withdrawal is complete, and buprenorphine should be initiated after patient is in mild to moderate withdrawal (as per COW's scale).
  - Methadone and buprenorphine can be used for medically supervised withdrawal and continued for maintenance treatment.
  - All three medications have evidence for reducing cravings.
  - Naltrexone should not be prescribed in pregnancy.

- Consider structural disparities for vulnerable populations when initiating MAT
  - Studies demonstrate existing stigma that medical providers have towards patients with OUDs and towards MAT. Be aware of your own implicit biases and colleagues’ biases. Initiate conversations with colleagues if you notice unwarranted obstacles in place for initiating MAT for a patient.
  - Be aware of existing structural disparities that impact access to MAT for structurally vulnerable populations, including people of color, LGBTQ+ populations, and different
age groups. Use knowledge of these disparities and practice cultural humility when assessing a patient and when offering specific MAT.

- Example 1: Despite similar rates of OUD, Black American patients are less likely to be offered MAT, and even when offered, are much less likely to receive buprenorphine prescription than their White American counterparts (even in a study controlling for age, sex, and type of payment).

- Example 2: LBGTQ patients have special medical considerations in MAT initiation including whether they are taking Prep for exposure prophylaxis, whether they may be living with HIV and taking antiretroviral therapy (ART), and whether they are on hormone therapy. Interactions with these medications should be assessed and conversations around appropriate clinical follow up are important.

  - Engage patient with open, nonjudgmental questions around their beliefs around MAT. Patients may have their own biases around MAT and OUD; if discovered, offer nonjudgmental psychoeducation while validating their concerns.
  - Make sure to offer interpreters for conversations if needed for evaluation and MAT discussion.
  - Assess for structural vulnerabilities that may impact a patient’s access to ongoing MAT and incorporate those obstacles when pursuing resources for a patient after discharge.
  - When initiating MAT, coordinate with case management to connect patients with appropriate level of continued OUD treatment services on discharge that incorporates patient cultural, language, and social preferences.
  - Be aware of limitations in different MAT choices.
    - Methadone is only prescribed in structured opioid treatment programs (OTPs).
    - In OTPs, patients initially must be seen daily; over time they may be able to get take-home doses. OTPs can be useful for patients requiring structure and easy access to substance use counseling; however, they can be harder to access for patients living in rural areas and for those with limited transportation options due to socioeconomic factors.
    - Buprenorphine can be induced faster than methadone and can be more accessible if there are certified providers in patient’s area. It is available in OTPs and office settings, and no longer requires a waiver for prescribing.

- Whether or not MAT is initiated, offer supportive measures to ameliorate symptoms of opioid withdrawal, including anxiety, insomnia, nausea/vomiting, diarrhea, pain, and autonomic symptoms (see Table 3).
## Table 2: MAT Options and Initiation for Opioid Use Disorder

</thead>
<tbody>
<tr>
<td><strong>Mechanism of Action</strong></td>
<td>Mu opioid receptor agonist Weak NMDA agonist</td>
<td>Partial mu opioid receptor agonist</td>
<td>Mu opioid receptor antagonist</td>
</tr>
<tr>
<td><strong>Uses</strong></td>
<td>Medically supervised withdrawal, maintenance MAT</td>
<td>Medically supervised withdrawal, maintenance MAT</td>
<td>Prevention of relapse to opioid misuse, following medically supervised withdrawal</td>
</tr>
<tr>
<td><strong>Formulations and Typical Dose range</strong></td>
<td>Oral: 20-200 mg daily</td>
<td>Sublingual tablet: 2-32 mg daily</td>
<td>Oral: 50 mg daily</td>
</tr>
<tr>
<td></td>
<td>Sublingual film, tablet (in combination with naloxone): 2/0.5-32/8 mg daily</td>
<td>Subcutaneous injection and Subcutaneous implant – not typically started in hospital</td>
<td>Intramuscular injection: (Vivitrol) 380 mg every 28 days</td>
</tr>
<tr>
<td><strong>Possible Adverse Effects</strong></td>
<td>Most common: Constipation, sedation, hyperhidrosis, dizziness, nausea and vomiting&lt;br&gt;Concerns: respiratory depression, QT prolongation, sexual dysfunction, orthostatic hypotension and syncope, misuse potential, neonatal abstinence syndrome&lt;br&gt;As a full opioid agonist, risk of overdose symptoms if titrated too quickly. Check drug interactions given Cy3A4 metabolism.</td>
<td>Most common: Constipation, nausea and vomiting, hyperhidrosis, insomnia, blurred vision, Orthostatic hypotension, respiratory depression (particularly combined with benzodiazepines or other CNS depressants), misuse and misuse potential, neonatal abstinence syndrome&lt;br&gt;Implant: Nerve damage during insertion/removal, accidental overdose, or misuse if extruded, local migration or protrusion</td>
<td>Most common: Nausea and vomiting, anxiety, insomnia, headache elevated LFTs, muscle and joint cramps&lt;br&gt;Concerns: precipitated opioid withdrawal, hepatotoxicity, depression, suicidality, anorexia /decreased appetite, or other appetite disorders</td>
</tr>
<tr>
<td><strong>Patient already on MAT admitted to hospital</strong></td>
<td>Verify outpatient methadone dose with OTP program, continue if verified unless medically contraindicated</td>
<td>Verify outpatient dose, consider transition to methadone if patient requiring acute pain management/sedation with opioids, otherwise continue unless medically contraindicated</td>
<td>Discontinue if patient will require opioid medication for pain/sedation, monitor for withdrawal precipitation</td>
</tr>
<tr>
<td></td>
<td>“Start low go slow”&lt;br&gt;Day 1: 10 to 20 mg total, MDD 30 mg&lt;br&gt;Day 2+: Increase slowly by 5 mg every few days in response to symptoms of opioid withdrawal and level of sedation at the peak plasma level 2 to 4 hours after dosing.&lt;br&gt;Stabilization after 4-5 weeks</td>
<td>Initiate while patient is in mild-moderate withdrawal.&lt;br&gt;Day 1: start at 2-4 mg buprenorphine (tab, film), MDD 8mg.&lt;br&gt;Day 2-3: Increase additional 2 to 4 mg every 2 hours up to approximately a 16 mg total daily dose to treat continuing opioid withdrawal.&lt;br&gt;Stabilization after several days</td>
<td>Patients have completed withdrawal and are opioid free for 7 days (short acting) and up to 14 days (long acting). Better evidence for injection vs daily oral</td>
</tr>

<table>
<thead>
<tr>
<th>Symptoms</th>
<th>Medication</th>
<th>Dosing</th>
<th>Notes</th>
</tr>
</thead>
</table>
| **Autonomic Symptoms**          | Clonidine   | Day 1: 0.1–0.2 mg every 4–6 h with a maximum dose of 1.2 mg          | • May also treat anxiety, restlessness, pain  
• IV administration and 7-day patch available  
• Monitor for hypotension, sedation                                                                   |
|                                 |             | Day 2 onward: taper by 0.1–0.2 mg per day                            |                                                                                                                                     |
|                                 |             | Dose as needed if patient on MAT                                       |                                                                                                                                     |
|                                 | Lofexidine  | Day 1: 0.54–0.72 mg every 6 h (total daily dose 2.16–2.88 mg)        | • No generic in US so can limit accessibility  
• Monitor for hypotension, sedation  
• Dose-dependent QT interval prolongation; use with caution (eg, monitor baseline and post-dose electrocardiogram) |
|                                 |             | Day 2 onward: decrease each dose by 0.18 mg every 1–2 days           |                                                                                                                                     |
|                                 |             | Dose as needed if patient on MAT                                       |                                                                                                                                     |
| **Anxiety, irritability, restlessness** | Diphenhydramine | 50 to 100 mg orally every 4 to 6 hours as needed (maximum 300 mg daily) | • May also treat nausea, insomnia  
• Use reduced dose in hepatic impairment  
• IV and IM administration available                                                                 |
| **Abdominal cramping**          | Hydroxyzine | 25 to 100 mg orally every 6 to 8 hours as needed (maximum 400 mg daily) | • May also treat lacrimation, rhinorrhea, insomnia  
• Use reduced dose (50%) in renal or hepatic impairment  
• IM and solution administration available                                                                 |
| **Diarrhea**                    | Dicyclomine | 10 to 20 mg orally every 6 to 8 hours as needed (maximum 160 mg daily) | • IM administration available (lower doses are used)  
• Use with caution and reduce dose in renal or hepatic impairment                                                                 |
| **Nausea/vomiting**             | Bismuth     | ~524 mg orally every 30 to 60 minutes as needed (up to 4200 mg daily) | • Monitor for dehydration and maintain fluid levels with oral and/or IV hydration                                                  |
|                                 | Loperamide  | 4 mg orally followed by 2 mg after each loose stool (maximum 16 mg daily) | • Monitor for dehydration and maintain fluid levels with oral and/or IV hydration  
• Dose-dependent QT interval prolongation; use with caution (eg, monitor baseline and post-dose electrocardiogram) |
<p>|                                 | Ondansetron | 4 to 8 mg orally or IV every 12 hours as needed (maximum 16 mg/day)   |                                                                                                                                     |</p>
